Working Draft for Supporting Blueberry Revision of XML Recommendation (1.0) with Particular Emphasis on Ethiopic Script and Writing System

November 2001

Authors/Editors:

Samuel Kinde Kassegne (Nanogen, UC San Diego, Engg Ext.) <bikila_97@yahoo.com>
Bibi Ephraim (Hewlett Packard) <thisbibi@yahoo.com>

Abstract

This document contains XML example codes, surveys and recommendations that support the need for Ethiopic script-based XML element type and attribute names in Amharic, Afaan Oromo, Tigrigna, Agewgna, Guragina, Hadiya, Harari, Sidama, Kembatigna and other Ethiopian languages that use Ethiopic script.

Status of this Document

This document is an initial working draft that is to be widely circulated for comment from the Ethiopic XML Interest Group and the wider public. The document is a work in progress.

Table of Contents

1. Scope

The work reported in this document contains XML example codes, surveys and recommendations that support the need for a revision of current XML standards to allow Ethiopic-based XML element type and attribute names in Amharic, Afaan Oromo, Tigrigna, Agewgna, Guragina, Hadiya, Harari, Sidama, Kembatigna and other Ethiopian languages that use Ethiopic script.

The Ethiopic XML Interest Group (formally called EthiopicXML Specifications Working Group) was established in July 2001 and aims to:

1. Support the Blueberry draft proposal that addresses the need for a revision of current XML standards to allow XML element type and attribute names in scripts such as Ethiopic that had their character sets included in Unicode only in version 3.0 and later.

2. Create and consolidate working groups and organizations with interest in Ethiopic and XML.

3. Educate the public on the need for Ethiopic extensions to XML for eCommerce, literature, education, and research applications. Also encourage the development of native XML grammar and vocabulary for a variety of applications in Ethiopic. This will include work in the major languages of the country, namely, Amharic, Afaan Oromo, Tigrigna and others.

4. Bring the topic for wider discussion that will include Ethiopic linguists, church personalities, academics and students of Ethiopian languages.

5. Finally, submit the draft proposal to the W3C XML Core working group.

2. Introduction

The current version of XML (V 1.0, Edition 2.0) is based on character standards of an older version of Unicode (v 2.0). Over the years, however, Unicode has evolved to newer versions that have added a number of character sets from various scripts around the world. As a result, not all character sets defined and standardized in Unicode 3.1 can be used as XML names such as element type names, attribute names, processing instruction targets, and the like. This has prevented a fully-native XML markup ability in Ethiopian languages such as Amharic, Afaan Oromo, Tigrigna, Agewgna, Guragina, Hadiya, Harari, Sidama, Kembatigna, etc which use Ethiopic script.

The so-called Blueberry revision of XML that addresses this issue affecting Ethiopic, Syriac, Myanmar, Ogham, Runic, Sinhala, Thaana, Yi and other scripts was recently proposed by the World Wide Web consortium (W3C) XML Core working group. The

latest version of the Blueberry draft document is published at http://www.w3.org/TR/xml-blueberry-req.

This work, therefore, is in response to the Blueberry requirement and deals with the demonstration and proposal for standardization of Ethiopic-based element type and attribute names in Amharic, Afaan Oromo, and Tigrigna languages.

3. Objectives

Through sample XML codes and DTDs (Document Type Definitions) for various applications (eCommerce, telemedicine, and calendar), we demonstrate that the use of non-Ethiopic script or transliteration is inadequate, inconvenient and in some cases erroneous for XML documents marked-up for use by speakers of one or more of the major Ethiopian languages. The examples codes include schemas based on transliteration and translations through the Latin script.

We also demonstrate that through the use of example XML codes and DTDs, hypothetically supported by Unicode 3.1, correct Ethiopic XML documents can be marked-up.

Further, we include an example (telemedicine) that demonstrates a real need for support in XML for Ethiopic name tags.

A review of the status of Romanization (the use of the Latin alphabet to represent Ethiopic-script languages) in both HTML and XML languages, how widespread it is, what standardization exist, if any, and how readily it is understood is included as a starting point.

4. Review of Status of HTML and XML Applications in Ethiopic

4.1. Evolution of Ethiopic Content in HTML

A review of the story of development of HTML markup in Ethiopian languages, we feel, will provide an appropriate and helpful insight how XML markup for Ethiopian languages will evolve. To aid this review process, we had carried out a survey of major Ethiopian web sites.

Ethiopian web sites started with HTML markups around 1994 and 1995 and were naturally limited to, in almost all the cases, to contents written in the English language. Whenever the need arose for writing in Ethiopic script, either image files were used or in the more sophisticated but awkward cases, partial Ethiopic fonts that fit into ASCII table were used. The introduction of transliteration by D. M. Yaqob, et al provided a number of news web sites with a clever option to markup their pages in Ethiopic [5], [6]. Further, the introduction of an Ethiopic character set and character code conversion algorithms and utilities by the same authors has also helped a number of web sites develop web contents in Ethiopic script. The **Ethiopian Headlines News** web site is an early and consistent user of such **transliteration** and "**conversion**" solution. **EthioIndex**, a news search site is a recent addition to the pool of transliteration and conversion users.

Over the past 18-24 months, encoding using Ethiopic Unicode character sets has slowly been introduced. Abass developed the so-called "**Ethiopia Jiret**" Unicode TrueType font [11] that consists of Ethiopic and Latin-1 blocks. The Ethiopic block confirms to the Unicode 3.0 standard. GF Zemen is another Unicode font for Ethiopic content. Examples of sites that use Unicode encoded Ethiopic character sets are **Senamirmir** and **Ethiopian Headlines News**.

While transliteration, conversion and now Unicode encoding of Ethiopic character sets had introduced an interesting and helpful solution in HTML marked-up pages for contents in Ethiopic, the majority of the major Ethiopian web sites still continue to employ awkward image files to display Ethiopic characters. In the case of **Seleda**, a popular monthly art and literature site targeting Ethiopians in the Diaspora, transliteration has been limited to depicting Ethiopian language words in their Latin transliteration equivalence. **MediaEthiopia**, another popular site with readership in both inside and outside Ethiopia uses image files for displaying documents written in Amharic and Afaan Oromo. Again, it needs to be mentioned that encoding using Ethiopic Unicode character sets is at its infancy and we expect it to be widely used in the next 3-5 years.

We feel various factors contribute to the rather non-uniform solution to the problem of HTML rendering in Ethiopic. The major problems are, however, the lack of any easy to use Ethiopic-based HTML software (including Unicode-based software) and the presence of numerous fonts and character encoding procedures. Despite the introduction of standards by bodies like **CEC** (Committee for Ethiopic Computing) and **ECoSA** (Ethiopian Computer Standards Association), the problem still persists at a large scale.

4.2.   Ethiopic and XML

Coming back to XML, to date, there is no publicly available data on the use of XML for marking-up web pages using any of Ethiopia's major languages. The survey in this report is the first such survey. This survey of major Ethiopian web-sites carried out by the authors of this report suggest that, at this point, HTML remains the markup language of choice in almost 100% of the sites with XML usage limited to one or two experimental sites. Our survey indicated that none of these major web sites have implemented XML yet.

However, the proliferation of well-architectured Ethiopian eCommerce sites like **AnythingONETHIOPIA** and **EthioTrade** and the slow but steady adoption of both consumer and B2B eCommerce practice suggests that the demand for XML markups for content and data in Ethiopic script will reach a critical mass in the near future. Further, we believe that the .NET strategy of Microsoft will ultimately not only encourage but also force introduction of Ethiopic software solutions based on XML.

With regard to the current limitation of XML 1.0, using the story of HTML markup language in Ethiopic as a guide, one may be tempted to extrapolate that transliteration and "conversion" at the server side may provide a way-around for hybrid XML markups in Ethiopic. However, XML documents are not merely documents but contain valuable data that are and should be amenable to manipulations of any sort the user wishes. Therefore the issue of usefulness takes precedence over a simple rendering in native Ethiopic script. In other words, unlike HTML where it is adequate, transliteration, in the context of XML, faces the additional burden of providing meaningful and structured data sets in addition to correct rendering in Ethiopic script. Therefore, the use of transliteration in hybrid XML document markups in Ethiopic, we feel, will be very much resisted by content providers, eCommerce sites and Ethiopic researchers and linguists for the simple but critical reason that it fails to address the major requirement of XML marked-up documents, i.e., providing a mechanism to manipulate data in a structured, accurate and non-ambiguous fashion.

Looking forward, the two areas where we see XML finding immediate use among Ethiopic script users are eCommerce and telemedicine. ECommerce application in Ethiopic, we propose, will follow the overall industry's trend as the need for presentation of structured data in eCommerce is universal. On the other hand, the promise of telemedicine is more relevant in least developed nations such as Ethiopia, where there is single physician for 100,000+ people. It is now well accepted that telemedicine holds a pragmatic promise to alleviate some of the most common infrastructure problems in medicine in developing countries. One can imagine remote villages connected to medical centers via wide area networks where appropriate medical personnel could remotely diagnose and prescribe remedies. Further, one can imagine the development of systems and tools that transmit medical symptoms and conditions from remote locations to medical centers for advice and resolution. XML has the potential to be a tool of choice for exchange of such information among the various fragmented medical institutions.

Table 1 contains a list of major Ethiopian news, information, research and community sites that were reviewed for this work. While there are hundreds of thousands of web sites related to Ethiopia [Google.com returned about 1.54 million pages when searched under the keyword "**Ethiopia**"], only the most important and representative web-sites were included in this survey.

The term "**transliteration**" as used here to describe support for Ethiopic content applies to transliteration and "**conversion**" schemes applied both at the server-level [a good example being **Ethiopian Headlines News**] and at the individual page level. The determination on the use of XML was based on the issue of availability of structured data at the sites. Our survey indicated that none of the sites covered in the survey use XML markup to present documents with structured data.

Table 1. Use of HTML and XML in Ethiopic Script in Major Ethiopian web-sites.

5. Hybrid XML Document Markups in Ethiopic

With the current XML 1.0 recommendations, Ethiopic script users are restricted to using either Latin script with English translation or Latin script with transliteration for defining their XML tags and attributes. Theoretically, it could be argued that translation could offer a quick and dirty short cut for helping native markups. Along the same lines, a case could be made for, at least hypothetically, the use of transliteration to help native markup.

5.1. Examples:

The following examples (A-E) demonstrate how the use of Latin script in translation and transliteration to define tags and attributes for an Ethiopic based XML document could be employed at least hypothetically. Here, we have used documents written in some of the major Ethiopian languages such as Amharic, Afaan Oromo, and Tigrigna. Example D, demonstrates the use of a transliteration based on the proposals of Yakob, et al [5], [6].

I. <u>Example A - Ethiopian Calendar Data in Amharic using Amharic-English translation</u>

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE HybridEXMLETCalendar SYSTEM
"HybridEXMLETCalendar.dtd">
<yabeshakalender>
        <qen> 25 </qen>
        <ilet> እሁድ </ilet>
        <beal_qen> ስላሴ </beal_qen>
        <wer> ግንቦት </wer>
        <yeAbeshaamet>1955</ yeAbeshaamet>
        <yezemensim> ዘመነ ዮሀንስ </yezemensim>
</ yabeshakalender >
```

The DTD file, HybridEXMLETCalendar.dtd, will look like this:

```
<!DOCTYPE yabeshakalender [
<!ELEMENT  yabeshakalender  (qen,ilet,beal_qen,wer,
yeAbeshaamet, yezemensim*)>
<!ELEMENT qen (#PCDATA)>
<!ELEMENT ilet (#PCDATA)>
<!ELEMENT beal_qen (#PCDATA)>
<!ELEMENT wer (#PCDATA)>
<!ELEMENT yeAbeshaamet (#PCDATA)>
<!ELEMENT yezemensim (#PCDATA)>
]>
```

Note: The name of a "**tabot**" could interchangeably be used with "**beal_qen**"; even though "**beal_qen**" is more generic and includes all holidays.

Further, the Ethiopian calendar data set could be expanded to contain attributes with the equivalent Gregorian calendar system as shown below.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE  HybridEXMLETCalendar SYSTEM
"HybridEXMLETCalendar.dtd">
<yabesha_ina_ferenj_kalender>
        < yabesha_qen> 25 </ yabesha_qen>
        <yeferenj_qen> 2 </ yeferenj_qen>
        <ilet> እሁድ </ilet>
        <beal_qen> ስላሴ </beal_qen>
        <yabesha_wer> ግንቦት </yabesha_wer>
        <yeferenj_wer> ሰኔ </yeferenj_wer>
        <yeAbeshaamet>1955</ yeAbeshaamet>
        <yeFerenjochamet>1963 </ yeFerenjochamet>
        <yezemen sim> > ዘመነ ዮሀንስ </yezemensim>
</ yabesha_ina_ferenj_kalender >
```

Again, the DTD file, HybridEXMLETCalendar.dtd, will look like this:

```
<!DOCTYPE yabesha_ina_ferenj_kalender [
<!ELEMENT yabesha_ina_ferenj_kalender (yabesha_qen,
yeferenj_qen,
                ,ilet,beal_qen, yabesha_wer, yeferenj_wer,
yeAbeshaamet,
                yeFerenjochamet , yezemensim*)>
<!ELEMENT yabesha_qen (#PCDATA)>
<!ELEMENT yeferenj_qen (#PCDATA)>
<!ELEMENT ilet (#PCDATA)>
<!ELEMENT beal_qen (#PCDATA)>
<!ELEMENT yabesha_wer (#PCDATA)>
<!ELEMENT yeferenj _wer (#PCDATA)>
<!ELEMENT yeAbeshaamet (#PCDATA)>
<!ELEMENT yeFerenjochamet (#PCDATA)>
<!ELEMENT yezemensim (#PCDATA)>
]>
```

II. <u>Example B - Ethiopian Calendar Data in Afaan Oromo Language using Afaan Oromo-English translation</u>

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE  HybridEXMLETCalendar SYSTEM
"HybridEXMLETCalendar.dtd">
<yabeshakalender>
        <guya> 25 </guya>
        <iletijeda> ዲልባታ </iletijeda>
        <beal_qenifu> ስላሴ </beal_qenifu>
        <bati> ኤብላ </bati>
        <yeAbeshaawaga>1955</ yeAbeshawaga>
        <yezemen sim> ዘሜነ ዮሀንስ </yezemensim>
</yabeshakalender >
```

III. <u>Example C - Ethiopian Calendar Data in Tigrignna Language using Tigrignna -English translation</u>

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE  HybridEXMLETCalendar SYSTEM
"HybridEXMLETCalendar.dtd">
<yabeshakalenderti>
        <mealti> 25 </mealti>
        <ilet> ሰንበት</ilet>
        <beal> ስላሴ </beal>
        <werhi> ግንቦት </werhi>
        <ametbeEthiopiaAkostasira>1955</
ametbeEthiopiaAkostasira >
        <yezemen sim> ዘመነ ዮሀንስ </yezemensim>
</yabeshakalender >
```

Example D - Address Data in Amharic using transliteration

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE  HybridEXML SYSTEM
"HybridEXML.dtd">
<adraxa>
        <kfle hager> ሽዋ </kflehager>
        <wereda>16</wereda>
        <qebelE>07</qebelE>
        <bEt>475</bEt>
        <ketema> አዲስ አበባ </ketema>
</adraxa>
```

V. **Example E – Application of XML in Telemedicine using Romanization**

In the Ethiopian context, given the particular unique and ambiguous ways of describing medical conditions/symptoms, translations, transliteration and Romanization could insert a level of misrepresentation. Example E presents an example of such a case.

Let us look at an example of a stomach ache being reported through a telemedicine system. An example DTD for transmission of type of ailment could look like:

```
<!DOCTYPE Beshita [
<!ELEMENT                                    Beshita
(ayenet,mekekit,lesentgeze,yebetesebtarik*)>
<!ELEMENT ayenet (#PCDATA)>
<!ELEMENT meleket (#PCDATA)>
<!ELEMENT lesentgize (#PCDATA)>
<!ELEMENT yebetesebtarik (#PCDATA)>
]>
```

Almost all the terms used in this particular data set could potentially be written in many different ways depending on the particular style of the author. For example, "**beshita**" [translation: ailment] could be spelled also as "**beshta**". Similarly, "**ayenet**" as "**aynet**", "**melekt**" as "**milikit**" or "**mlkt**", and "**lesentgize**" as "**lesntgze**".

5.2. Discussions

While the schemas shown above demonstrate that a hybrid (English and Ethiopic) XML document could be written with some effort using translation and transliteration, the following handicaps make the usefulness of such "work-around" very difficult, cumbersome and impractical.

5.2.1. **Switching between two scripts**. The Ethiopic XML document author will have to switch between Ethiopic and Latin scripts for each and every attribute of the document.

5.2.2. **Translation skills**. With regard to translation, the usefulness of the data set depends on the translation skills of the author. For example, some unique Ethiopian concepts like "**tabot**" [**ታቦት**] do not have an equivalent English (or any foreign language) words. Here, we had used the word "**beal qen**" [**በኣል ቀን**] as an equivalent translation; but this word just means a "**holy day**" and does not necessarily establishes the distinction between a regular holiday like Ethiopian New Year (**Meskerem 1**) and a "**tabot**" like **Lideta/Kidist Mariam** which also falls on the first of each month. Therefore, this attribute could potentially be carrying a wrong data.

5.2.3. **Romanization styles**. As shown through Example E (telemedicine example), the Romanization style of the author has a significant influence on how the attributes are presented. There are simply many styles of writing Amharic, Afaan Oromo or Tigrigna words in Latin script; none of them being more correct than the other.

5.2.4. **Cultural sensitivity.** The powerful Ethiopian church and its army of linguists have historically been very much opposed to any attempt to replace Ethiopic script usage by even traces of Latin script. The Ethiopian Church has regarded itself as the keeper of the Ethiopic (also called Geez) script since the early days of its foundation in the late 6th and 7th Century. Over the years, all attempts to modernize the script even with the blessing of powerful political readers have failed. We see transliteration and facing the same fate. A detailed account of such prior attempts and the church's sensitivity to script issues is given by a classic publication of Abraham Demoz [10].

5.2.5. **Lack of standard and acceptance**. Currently, apart from the work of a single group of researchers, transliteration is not a widely accepted practice. As a result, there simply isn't even

agreement on what transliteration scheme to adopt. A case in point is, for example, the different ways the Ethiopian name ያቆብ is spelled and transliterated. Variations of this include, Yacob, Yaqob and Yakob. It is interesting to note while the letters "c", "q", and "k" have been used to represent the Ethiopic explosive sound, "ቆ" ("qwo"), none of them actually is more accurate than the other.

Another example that demonstrates the lack of agreement and conventions is the Amharic word for address (i.e., አድራሻ). The "sha" sound in Amharic is usually transliterated, as seen in the at least 50 years tradition of Ethiopian English newspapers like the Ethiopian Herald, with the equivalent "sha" in English. However, as Example D taken from Reference [6] shows there is at least one transliteration scheme where "x" has been used to transliterate the Amharic sound, "sha". Further, the transliteration for this particular sounds is identical to what the Somali language (a language with no history of script of its own) has adopted in its Latin-based writing system. This, in our opinion, lacks sensitivity to Ethiopian long-held pride in a written language by proposing a solution that basically equates it to languages with no written history. This fact alone can guarantee, in our opinion, resistance from Ethiopian linguists and Church officials, two important bodies traditionally regarded as the guardian of the Ethiopic (Geez) script.

6. Fully-Native XML Document Markups in Ethiopic

The Ethiopic script was formally adopted by the ISO in Unicode 3.0. Here, we use the Unicode (3.0) representations of Ethiopic characters to demonstrate the application of a potentially fully-native markup for Ethiopic XML documents.

6.1. Examples

We will use the same example used in Section 5 (i.e., Example A) to demonstrate this.

I. <u>Ethiopian Calendar Data in Amharic in Fully-Native XML markup</u>

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE HybridEXMLETCalendar SYSTEM
"HybridEXMLETCalendar.dtd">
< የአበሻካሌነደር>
        < ቀን> 25 </ቀን>
        < እለት> እሁድ </እለት >
        <በአል ቀን > ስላሴ </ በአል ቀን >
        < ወር> ግንቦት </ወር >
        < የአበሻ አመት>1955</ የአበሻ አመት>
        < የዘመን ስም > ዘመነ ዮሀንስ </የዘመን ስም >
</ የአበሻካሌነደር >
```

The DTD file, HybridEXMLETCalendar.dtd, will look like this:

```
<!DOCTYPE የአበሻካሌነደር [
<!ELEMENTየአበሻካሌነደር
(ቀን,እለት,በአል ቀን,ወር,የአበሻ አመት,የዘመን ስም*)>
<!ELEMENT ቀን (#PCDATA)>
<!ELEMENT እለት (#PCDATA)>
<!ELEMENT በአል ቀን (#PCDATA)>
<!ELEMENT ወር (#PCDATA)>
<!ELEMENT የአበሻ አመት (#PCDATA)>
<!ELEMENT የዘመን ስም (#PCDATA)>
]>
```

6.2. Discussions

The example in Section 6.1 demonstrates that a fully-native XML markup in Ethiopic script provides a cleaner solution.

Particular advantages of such a fully-native XML markup in Ethiopic script include:

- Clarity of data definition. With fully-native markup, there will not be any confusion on what the author uses to represent a certain data.
- Better readability of XML codes by humans. This is indeed one of the requirements in XML 1.0 recommendations.
- Ease in writing a good and clean XML code with no frequent switching of scripts.

7.   Conclusions and Recommendations

The example schemas in Section 5 demonstrated that a hybrid (English and Ethiopic) XML document could be written with some effort using translation and transliteration. However, we have demonstrated that, its usefulness is seriously hampered by the following handicaps described in depth in Section 5:

I.   Inconvenience of switching between two scripts.

II. The translation skills of the author and user of XML pages have a large influence on the usefulness of the data and document.

III. The numerous personal preferences and styles of writing Ethiopic words in Latin script also have a large influence on the usefulness of the data and document

IV. Cultural sensitivity has historically been a major issue in Ethiopia [10]

V.   Lack of standard and acceptance of transliteration poses a problem

VI. Need for equal representation of scripts. The notion of XML not being able to support complete native markup for certain scripts is very hard to justify as it seems to carry a negative stigma of unfairness and lack of equal representation of writing systems around the world. Discriminating against languages simply because their scripts were not encoded in Unicode 2.0 is inherently unjustifiable.

VII. One of the specific goals mentioned in XML 1.0 specification states that "XML documents should be human-legible and reasonably clear". For users of Ethiopic, Syriac, Myanmar, Ogham, Runic, Sinhala, Thaana and Yi scripts, this requirement is violated. Certainly, such contradictions are extremely hard to justify.

Further, in Section 6, we have demonstrated that a fully-native markup for Ethiopic will encourage the use of XML markup for Ethiopic use in education, media, eCommerce and the like.

In the final analysis, we propose that a hybrid markup will in fact stifle the use and proliferation of Ethiopic script use in XML documents. A completely native XML markup in Ethiopic, we propose, is the justifiable solution to the proliferation of useful Ethiopic content and data in XML.
